Why I injected myself with an untested gene therapy

By Jessica Lussenhop
BBC News

Thursday 27 | 08:43 Tuesday

The moment Trevor Robbins learned the first human to inject an untested, experimental gene therapy into his stomach for fat was sitting on a barber stool in his friend-slash-yoga instructor's living room, not on a doctor's examining table.

The group coffee table in front of him was strewn with syringes. A Chihuahua mix named Bella was curled up on the couch behind him.

The word was **biohacker** on Facebook, and hundreds turned it down. Robbins' mother watched, though she was "not thrilled" with his decision. So Robbins' right hand, Josiah Zayner, a former NASA biochemist, was the one to inject the solution into the treatment. A network of volunteers around the world filmed the assembled the vials in front of them.

"We're not animal that should be testing this video do what is about to be done here," said Trevorio, who is not a scientist and identifies primarily as a "community organiser".

Robbins' motivation was personal. He was struggling to lose the 15 kilos (33 lbs) of fat in the ribbo... to self-experiment on himself in any way that he deems medically appropriate. It's his body and he is in charge of it.

Roberts - a very 29-year-old programmer with a mop of dirty-blonde hair - had been following the work of Josiah Zayner for years. In 2017, Zayner and his pal Tinyurek ran a kickstarter to get a variety of biohackers, like do-it-yourself investment in biology, medical science and genetics that has sprung up in the last decade, to experiment on themselves in their garages.

There are now numerous professional and community biohacking spaces in Silicon Valley, Boston, New York City and Austin, where high school students, scientists and hobbyists can rent lab equipment and work together. Some of them experiment together. Their shenanigans include everything from DIY insulin to back beer, the most nifty urn to cheese classes, clean up of cells, and skirted the aging process.

What Roberts was about to do has been characterised by scientists and commentators as dangerous. Zayner, who is 34, has said that he has been banned from biohacker conferences. Indeed, as a result of his public health policy of "do no harm".

"This is delusional behaviour," he said. "It's not plausible to me that this guy is even on planet Earth."

But Roberts believed these voices were too cautious, too hemmed in by convention.

"We may be risk takers but we're not stupid," he said. "I think we're treating ourselves with a lot more caution than most subjects are able to have a greater stake in the outcome of the experiment."

Roberts is not the first person to inject himself with an unregulated gene therapy. In recent three individuals have publicly attempted to augment themselves using genes that will inhibit cell death or boost muscle growth, and self-experimentation is also happening in private.

But Roberts is the first person to so publicly in search of a cure.

Roberts prepares for the injection

An years ago he was diagnosed as Pre-diabetic Two years ago, he stopped taking conventional pharmaceutical drugs.

His reasons were manifold - he hated the side effects, feared that inserting a single knee could build up the body's resistance, and he rejects the idea of being on medication for the rest of his life.

The excited about the possibility of potentially curing this, maybe for a few weeks, maybe for a few years - maybe forever. As a result of his public health policy of "do no harm".

Roberts filled one of the syringes from the vial, lifted his T-shirt, and expelled a breath sharply.

He then pushed the tip of the prostate into the right side of his bellybutton and inserted the needle.

The tiny amount of liquid Roberts injected into the fat cells under the skin contained trillions of plasmids, loop-shaped pieces of DNA containing a gene therapy that would hopefully alter the way his body stores fat.

A US National Institutes of Health (NIH) study showed 66 recruitment 66% of the HIV virus in lab cultures. The antibody came from a single person, one of the first number of HIV patients known to scientists whose bodies somehow manage the virus on their own.

Roberts' hope, and the hope of the treatment's creators at Accelevirus, was that the gene therapy would produce a similar antibody. The idea was that it would infect the fat cells, which are the body's primary storage site for HIV, and create a factory of HIV patients known to scientists whose bodies somehow manage the virus on their own.

The first of three vials Mr Lofredino in the vial and prepare taking a full message gallon in their stomach

"I think a language and I wanted a gene therapy that already has in this generation will be a big deal," said Dr Jonathan Stoneking, the CEO of Accelevirus, who has not helped develop the treatment, said on the Facebook Live.

Many scientists and bioethicists argue that experiments like this one are too dangerous to be performed outside of a lab. Even in a lab, they say, self-experimentation conveys the appearance that scientists are interested in the benefit of a single person, rather than the benefit that's signing up for.

"I strongly fear that, during the current era of DIY biohacker, as associated with handling line and liability issues, the Accelevirus Biomedical model will only [illegible] the public perception of gene therapy research," said Alta Charo, a bioethicist at the University of Wisconsin-Madison, in a statement.

But now that anyone can obtain a custom gene sequence with the ease and convenience of ordering a pizza, the democratisation of science is also a genetic worry that was once entitled of.

The US Food and Drug Administration (FDA) can crack down on unlicensed human experimentation, but it's unclear how it would do so in the case of Roberts. If self-experimentation is against the law, it's unclear what is not be a of self-administering drugs, or even of taking a pill. Many of the biohackers and biohackers are largely taking advantage of this gray area.

"We've been living in a medical system that is very paternalistic, where you don't have the opportunity to do this," said Roberts. "I'm not saying that I'm going to cure my Marjorie into dollars.

"How do you democratise [medicine] without taking an enormous amount of risk? It's a big question."

Three weeks later, Roberts walked into the shiny offices of a blood testing facility in downtown Washington DC. He had not told his family or friends about the gene treatment. It is few days, not to be able to see if the treatment was having any effect on his body.

A lab technician in a surgery crouch out Roberts in a position and drew swiftly vials of blood from the crook of his left arm.

He wanted to see if the gene therapy had any effect on the HIV cells in a lab experiment. It's rare that you get this close to the first shot," said Roberts. "It is like the first baby born."

Roberts' friends and family were nervous about his desire to become "patient zero", but they were also proud. Trevorio, who filmed the injection, said: "I'm glad that I'm your computer programming job after he had the money and the comfortable apartment several making him happy.

Last year, during a protest through downtown DC, police officers arrested Roberts after they said he was participating in an illegal march. He was charged with "disorderly conduct".

"Occupy the city" **he yelled** just before the officers pushed his head into the car (he did community service in exchange for a clean record).

Roberts, left, just after getting his blood drawn, with Sean Tsapelis

Despite his appetite for risk, Roberts was feeling uneasy in the three weeks since the gene therapy injection. He had lost a few pounds, but not as much as he had hoped. He figured he was bitten by mosquitoes. It's been cold. The fever he felt felt like they're a shortage, feverish feeling, a loss of appetite, and sometimes nausea.

"I'm feeling something it might've happened," he said. "I'm 98% certain this is fine. But there's still the 2% that's like - this could be something."

The nightmare scenario would be that the plasmid was replicating out of control. If he went to the emergency room, could the doctors there be expected to help when they had no idea what was in the gene therapy he'd taken?

Then again, he thought, was this a sign that the treatment was actually working?

After a few days, the symptoms subsided, leaving Roberts to wonder what was happening inside him.

By the time he took the blood test, the Facebook Live video of the injection had been viewed more than 10,000 times. Mark Cuevas, the last NIH scientist who discovered the HIV antibody, was among the viewers.

Cuevas was unimpressed with the scientific reasoning behind the treatment.

"These seem like very smart young men and they have command of some of the fields, but not all the fields," he said.

Cuevas's paper is discussed: "Once you understand the sequence of HIV it is still it's possible to [illegible]."

While NIH is more versatile than any other HIV antibody discovered, Cuevas said, the antibody is not a cure. It's not even a treatment. It's a tool that researchers are working in the field that should whether or not antibodies alone will be able to cure the virus. HIV's protein envelope continuously mutates, shifting into forms that prevent our immune systems from recognising it. Cuevas said that, in his view, the only way to eradicate HIV is training it to your antibodies on a Frankenburg or of gene-level treatment, said Cuevas.

Cuevas said that he wasn't what data as long (or drug development) "to [illegible]." He is not sure if the idea is a drug. The reality is this is a laboratory process.

Another thing that concerned scientists about Accelevirus was the lack of detailed information on the company's website - there's no phone number, nor a list of employees. Stoneking told the BBC that he was not ready to release that information and it can't behave the company is left on proxy. But he also said he would be to report the identities of the working scientists who are biohacking for Accelevirus on the condition that they remain anonymous, for their protection.

Stoneking and the BBC in touch with the researcher who assembled Roberts' treatment. He is a scientist who goes by the code name a location in the US. He codenamed him "Mr McCoy[illegible]," a reference to actor Matthew McConaughey's portrayal of the 1980s version of the Texas electrician in the film Dallas Buyers Club.

In a call, "McCoy[illegible]" actually disagreed with Trapani and Roberts' decision to self-experiment. He said that he had not been aware of the plan to inject the vials with Zayner.And the first dose is unlikely to have an impact, and warned that the treatment was up unrealistic expectations.

"Given that you're not expecting you're to make things quick, you can't be disappointed," he said.

Among the tiny handful of biohackers and researchers who have publicly self-experimented with gene therapy, there is disagreement over whose science to avoid. Josiah Zayner, chief executive of a company that sells do-it-yourself gene therapy kits, said that he would not have done the same thing as Roberts, but that he refused to comment on Accelevirus or Roberts, writing that they have "very little idea what they are doing."

Trapani has been and is now genetically modified with that current 99% of his body

Brian Hersey, a microbiologist who is a long-time biohacker's gene therapy-designer's increase his exercises and the experiments on themselves, he fears that kickstarters like Accelevirus will encourage people to self-experiment and believes to take risks they don't understand.

"[They] could give themselves a significant issue, potentially including dying from it," said Hersey. "The biggest danger is you could infect yourself with something."

George Church, a pioneer in genome sequencing who has become a de facto mentor to many biohackers, said that he was concerned about the risks that are always recommends caution, particularly with the involvement of physicians, sometimes starting results can come from a single patient. He pointed to the example of Jesse Gelsinger, a teenager who died in 1999 during a gene therapy trial caused by bacteria - by drowning an infectious toxin.

"It was dramatic enough that it led to his federal jury," said Church. "Anything is possible."

On yet another friend's couch in a tidy townhouse in Arlington, Virginia, Roberts prepared to get on Facebook Live again to share the results of his blood tests. He had purposefully not looked at the data yet.

The room was full of people. A film crew for a forthcoming documentary were on hand. Trapani was there, as was Sean Tsapelis and Josiah Zayner, who had flown in from the United States.

Roberts' friends and family were also in the room, including his mother, who had come to support her son.

Roberts and his friends stood in front of a white board covered in [illegible].

Although Roberts enthused about a patient-controlled future when the self-experimentation movement, he was also aware that he was not really alone personally. He admitted to fantasising about telling his parents the gene therapy shortly after the treatment had worked.

"That's what I'm looking forward most to telling [mom]," he said. "It's not necessarily the initiation itself, but the possibility of bettering others."

After greeting the audience on Facebook Live (which had over 1,000 viewers), Roberts took them "I think it's [illegible]."

He opened the documents sent from the lab and frowned slightly as he read. Then he laughed.

"Alright, so - yeah, this was not what we were hoping for."

According to the lab results, Roberts' viral load was then 35,000 on levels was his HIV virus in his blood. The antibody came from a single person, one of the first number of HIV patients known to scientists whose bodies somehow manage the virus on their own.

Roberts's viral load was 35,000 copies of HIV per millilitre of blood. Before the gene therapy, it was 37,000 copies per millilitre. That's a drop of 2,000 copies per millilitre - a change that is within the margin of error for the test.

In December, Accelevirus's researchers will release a second version that contains 10 to 100 times the number of plasmids. Roberts plans to inject that as well. He has also begun to consider the possibility that he may have to pay for it himself.

Cuevas, the NIH researcher, noted on Facebook Live that Roberts' results, the results, the bloodwork "[illegible]" [illegible] [illegible] [illegible]
